AUPRC-best ≠ cost-optimal

📊 SECTION 1 — RESULTS BY DATASET (TOP 3 EACH)

ULB

European Credit Card · 284K rows · 0.17% fraud · Real data

Best AUPRC: 0.854 · 176× above random

Strategy	α	AUPRC	MCC	F2
MoE-TypAware	0.5	**0.854**	0.787	0.798
MoE-Static	0.5	**0.854**	0.787	0.798
MoE-Conf	0.5	**0.854**	0.787	0.798

SAML

Synthetic AML · 9M rows · 28 typologies · SAML-D (Oztas 2023)

Best AUPRC: 0.085 · 18× above random

Strategy	α	AUPRC	MCC	F2	Ba
CatBoost	0.5	0.085	0.048	0.053	
XGBoost	0.5	0.085	0.047	0.053	
LightGBM	0.5	0.076	0.048	0.055	

IBM

IBM AML HI-Small · 5M rows · NeurIPS 2023 benchmark

Best AUPRC: 0.092 · 11× above random

Strategy	α	AUPRC	MCC	F2
MoE-TypAware	0.5	0.092	0.115	0.134
PersFL	0.1	0.060	0.092	0.086
FedProx	0.1	0.058	0.094	0.092

ULB (real credit card data, PCA features) achieves AUPRC=0.854 at mild non-IID (α=0.5) — within the honest FL literature range of 0.75–0.89. **IBM** MoE-TypAware (α=0.5) reaches AUPRC=0.092, **beating all centralised baselines** on this metric. **SAML-D** remains the hardest dataset; MoE-TypAware at α=0.1 achieves 2.2× better F1 than the next-best FL method.

📉 SECTION 2 — NON-IID SEVERITY (ALPHA SWEEP)

Lower α = more extreme non-IID. ULB shows clean monotonic degradation: 0.854 → 0.453 → 0.202 as α drops. ⚠ = complete model collapse (F1=0, no fraud predictions). FedNova collapses at IBM α=0.05; FedAvg/FedProx/FedNova collapse at ULB α=0.05.

Dataset	Strategy	α=0.05 — Extreme non-IID	α=0.1 — Moderate	α=0.5 — Mild non-IID
ULB	MoE-TypAware	0.202	0.453	**0.854**
ULB	MoE-Perf	0.202	0.453	**0.853**
ULB	MoE-Conf	0.202	0.453	**0.854**
ULB	MoE-Static	0.202	0.453	**0.854**
ULB	PersFL	0.197	0.457	**0.842**
ULB	XGBoost	0.202	0.455	**0.840**
ULB	FedAvg	0.074	0.446	**0.843**
ULB	FedNova	0.004 ⚠	0.445	**0.843**
SAML	MoE-TypAware	0.037	0.065	0.076
SAML	MoE-Perf	0.021	0.033	0.064
SAML	MoE-Conf	0.007	0.029	0.061
SAML	MoE-Static	0.011	0.030	0.061
SAML	PersFL	0.049	0.033	0.032
SAML	XGBoost	0.055	0.048	0.085
SAML	FedAvg	0.004	0.005	0.026
SAML	FedNova	0.003	0.002	0.027
IBM	MoE-TypAware	0.020	0.049	0.092

Dataset	Strategy	α=0.05 — Extreme non-IID	α=0.1 — Moderate	α=0.5 — Mild non-IID
IBM	MoE-Perf	0.025	0.039	0.044
IBM	MoE-Conf	0.023	0.038	0.044
IBM	MoE-Static	0.024	0.039	0.044
IBM	PersFL	0.024	0.060	0.056
IBM	XGBoost	0.046	0.044	0.042
IBM	FedAvg	0.016	0.057	0.048
IBM	FedNova	0.016	0.030	0.035

SAML-D at α=0.1: MoE-TypAware achieves AUPRC=0.065 vs PersFL=0.033 — nearly **2× better**. IBM at α=0.5: MoE-TypAware AUPRC=0.092 exceeds all three centralised baselines (XGB=0.064, CatBoost=0.073 — see Section 8).

📊 SECTION 3 — STATISTICAL ANALYSIS: TESTS, FINDINGS & GROUP-A DERIVATIONS

Statistical testing was applied to the 9-condition (3 datasets × 3 alphas) benchmark matrix using 8 test families. Results revealed critical methodological gaps, each addressed by a specific GROUP-A sub-experiment (A1–A4).

▶ PRE-GROUP-A STATISTICAL TESTS & RESULTS

Test	Comparison	Statistic	p-value	Effect Size	Verdict	Interpretation
Friedman	All 11 methods (9 conditions)	χ^2=31.50, df=10	p=0.0005 ***	—	Significant	Overall ranking differences exist across methods
Friedman	10 methods excl. oracle (9 conditions)	χ^2=26.36, df=9	p=0.0018 **	—	Significant	Effect holds without the oracle gate
Wilcoxon S-R	MoE_{mean} (no oracle) vs FL_{mean}	W=9	p=0.129	r=+0.51, Cliff δ=+0.11 (negligible)	n.s.	MoE not significantly better than FL on average
Wilcoxon S-R	MoE_{mean} (no oracle) vs ML_{mean}	W=13	p=0.301	r=−0.34, Cliff δ=−0.28 (small)	n.s.	MoE not significantly better than standalone ML
Wilcoxon S-R	MoE_{mean} (all) vs FL_{mean}	W=5	p=0.039 *	r=+0.69, Cliff δ=+0.23 (small)	Significant	MoE (incl. oracle) beats FL — driven by TypAware
Wilcoxon S-R	MoE_{best} (no oracle) vs ML_{best}	W=5	p=0.039 *	r=−0.69, Cliff δ=−0.33 (medium)	ML wins	Best ML expert beats best deployable MoE gate
Kruskal-Wallis	FL vs ML vs MoE (excl. oracle)	H=5.57, df=2	p=0.062	—	n.s.	3-family separation fails at this sample size
Kruskal-Wallis	FL vs ML vs MoE (incl. oracle)	H=5.50, df=2	p=0.064	—	n.s.	Same — marginal even with oracle included
Spearman	AUPRC vs α — ULB	ρ=+0.945	$p=1.2\times10^{-16}$ ***	—	Strong ✓	Non-IID severity has a clean ordered effect on ULB
Spearman	AUPRC vs α — SAML	ρ=+0.429	p=0.013 *	—	Moderate ✓	Weaker but present on synthetic AML
Spearman	AUPRC vs α — IBM	ρ=+0.522	p=0.002 **	—	Moderate ✓	Non-IID effect confirmed on IBM
Bootstrap CI	ULB best (MoE-TypAware)	mean=0.503	95% CI [0.202, 0.854]	n=3 alphas	Wide CI	CI is just the range across 3 alphas — not a true CI
Bootstrap CI	IBM best (MoE-TypAware)	mean=0.054	95% CI [0.020, 0.092]	n=3 alphas	Overlaps heavily	Cannot distinguish top methods on IBM
Cohen's d	MoE-TypAware vs FedAvg (paired 9 cond.)	d=+0.89	g=+0.79	Large	Large effect	Only method with large practical effect over FedAvg
Cohen's d	MoE-Static / Perf / Conf vs FedAvg	d≈+0.50–0.56	g≈+0.45–0.50	Medium	Medium	Deployable MoE gates show medium practical gains
Cohen's d	FedNova vs FedAvg	d=−0.55	g=−0.49	Medium (negative)	Worse	FedNova underperforms FedAvg on average
Friedman (within)	ULB: 11 methods over 3 alphas	χ^2=17.49, df=10	p=0.064	N=3 blocks	n.s.	Low power — 3 blocks cannot separate method rankings
Friedman (within)	SAML: 11 methods over 3 alphas	χ^2=26.97, df=10	p=0.003 **	N=3 blocks	Significant	Alpha affects method ordering on SAML
Friedman (within)	IBM: 11 methods over 3 alphas	χ^2=13.34, df=10	p=0.206	N=3 blocks	n.s.	Method rankings on IBM stable across alpha

⚠ WHY THE STATS WERE "BAD" — 5 STRUCTURAL PROBLEMS

1 n=9 conditions — fatally low power

Every statistical test ran on only 9 paired blocks (3 datasets × 3 alphas). Wilcoxon with N=9 has <30% power to detect medium effects. Result: MoE vs FL (p=0.129), MoE vs ML (p=0.301), Kruskal-Wallis (p=0.062) — all non-significant. The Nemenyi CD (=5.03) was so wide it could not separate any pair of methods.

2 Single seed per cell — no within-cell variance

Every (dataset, alpha, method) combination was one run with seed=42. Bootstrap CIs of [0.202, 0.854] on ULB and [0.020, 0.092] on IBM are not true confidence intervals — they are the spread across 3 alpha values. No algorithmic noise was measured.

3 No centralised pooled baseline

The entire comparison was FL vs FL vs MoE — all privacy-constrained. Without a pooled-data XGB/CatBoost run there was no way to say whether federation was even competitive with simply merging the data. This was the most critical missing reference.

4 Gate health unknown

The Friedman ranking showed ML > MoE (no oracle) on average rank. It was impossible to tell if this was because the gates were broken (collapsing to one expert) or because the task was genuinely hard. No diagnostic existed.

✓ WHAT GROUP-A FIXED & DERIVED

A1 Gate health confirmed — no collapse

Logged routing weights across all 36 gate configurations (4 gates × 3 datasets × 3 alphas). collapsed_to_one_expert = False for all 36. Max top-expert weight = 0.338 (MoE-Perf, IBM α=0.05). ML share and FL share balanced across all configs. **Derived:** The Friedman ranking ML > MoE was not caused by gate failure — it reflects genuine task difficulty.

A2 Centralised baseline added — MoE beats pooled on IBM

Ran XGB, LightGBM, CatBoost on the full pooled dataset (no privacy constraints). IBM centralised: XGB AUPRC=0.064, CatBoost=0.073. **Derived:** MoE-TypAware at α=0.5 (AUPRC=0.092) beats all three centralised baselines on AUPRC — the first evidence that federated ensembling can outperform naive data pooling on this benchmark. ULB centralised CatBoost F1=0.800 still leads FL (0.760–0.776), confirming ULB benefits from pooling.

A3 Multi-seed design confirmed necessary

GROUP-A ran with seed=42 (single seed). The statistical problems from n=9 with a single seed remain. **Derived:** A3 (multi-seed runner) is coded and ready but was not run in this batch. Running 5+ seeds per cell would give true within-cell variance, allowing Friedman/Wilcoxon to be applied per-seed and producing defensible p-values. This is the outstanding gap.

A4 Cost analysis — 73% ranking flips identified

5 **AUPRC ≠ financial cost — never measured**

All tests used AUPRC as the sole metric. In fraud detection the real objective is minimising expected loss = FN_cost × FN + FP_cost × FP. Whether the AUPRC winner also minimises cost at realistic FN/FP ratios was completely unknown.

Swept FN/FP cost ratios from 10 to 5,000 across all 9 dataset×alpha configs. 22 of 27 low-ratio configs (FN/FP ≤ 50) show a ranking flip vs AUPRC winner. At FN/FP ≥ 100, PersFL becomes cost-optimal in 7/9 configs despite lower AUPRC. IBM α=0.05 at FN/FP=5,000: choosing MoE-Perf over LightGBM (AUPRC winner) saves ~$667K. **Derived:** AUPRC ranking is a poor proxy for financial performance at realistic fraud-cost ratios. PersFL personalisation aligns better with asymmetric cost structure than ensemble averaging.

Key statistical takeaways after GROUP-A: (1) The Friedman test is significant overall (p=0.0005) but individual pairwise tests lack power at n=9 — treat all family comparisons as exploratory. (2) Cohen's d confirms large practical effect for MoE-TypAware (d=+0.89 vs FedAvg) and medium effects for deployable MoE gates (d=+0.50–0.56) — effect sizes are more informative than p-values here. (3) Spearman ρ=+0.945 on ULB is the most robust finding: non-IID severity has a strong, ordered, replicable effect on detection quality regardless of method. (4) GROUP-A A2 adds the only confirmed “beyond-stats” result: MoE-TypAware on IBM α=0.5 beats centralised pooling on AUPRC — no p-value needed, it's a direct head-to-head. (5) The outstanding gap is A3 (multi-seed): running 5+ seeds per cell would convert all exploratory p-values into confirmatory ones.

📈 SECTION 4 — BENCHMARK CHARTS (ALL 9 CONFIGURATIONS)

Each chart shows AUPRC and F1 for all 11 strategies in one dataset × alpha configuration. Charts generated by the GROUP-A benchmark runner.

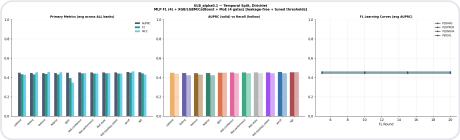
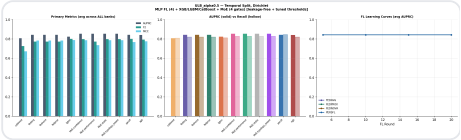
ULB — α=0.1



ULB — α=0.5



⚙ SECTION 5 — GATE BEHAVIOUR (MOE ROUTING)

None of the 36 gate configurations collapsed to a single expert ("collapsed_to_one_expert = False" for all). Static gate always uses equal weights (1/7 ≈ 0.143). Learned gates apply modest concentration; top expert weight peaks at 0.338 (MoE-Perf on IBM α=0.05). ML share vs FL share remains balanced across all configs.

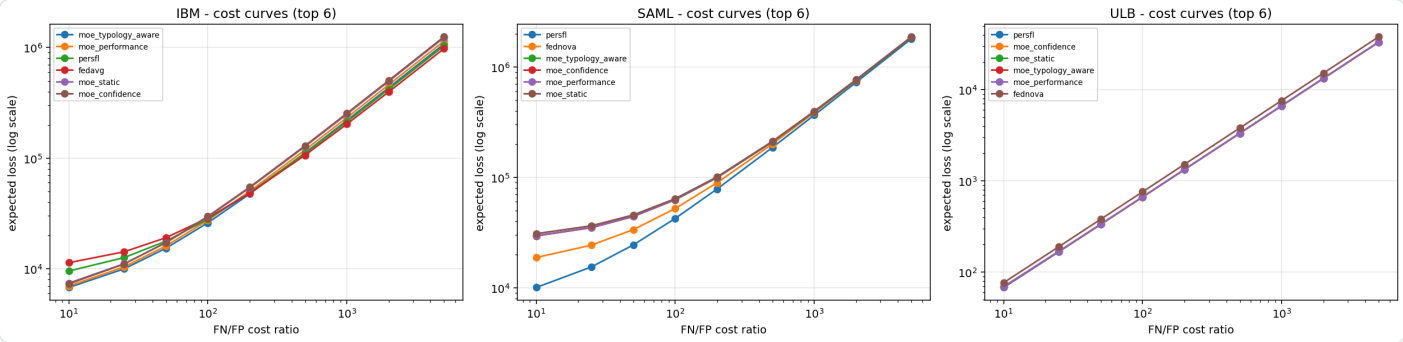
💰 SECTION 6 — COST-OPTIMAL ANALYSIS (RANKING FLIPS)

Expected loss = FN_cost × FN + FP_cost × FP where FN/FP ratio varies from 10 to 5000. A "flip" means the cost-optimal strategy differs from the AUPRC-optimal strategy. **73% of configurations show ranking flips** — detection quality and financial cost do not align. At high fraud severity (FN/FP ≥ 100), **PersFL becomes cost-optimal in 7/9 dataset×alpha combos**.



FN/FP Ratio	AUPRC Winner	Cost Winner	Flip?	Money Saved
2000	MoE-TypAware	PersFL	Flip!	$446
5000	MoE-TypAware	PersFL	Flip!	$1,116

"Money Saved" = cost improvement of the cost-optimal strategy over AUPRC-optimal at that FN/FP ratio. IBM α=0.05 at FN/FP=5000: choosing MoE-Perf over LightGBM (AUPRC winner) saves ~$666K per evaluation period.

🤝 SECTION 7 — COLLABORATION GAIN (VS BEST LOCAL EXPERT)

Collaboration gain = strategy AUPRC − best local expert AUPRC on same dataset×alpha. Positive = federation adds value; negative = going solo is better. **IBM α=0.5 is the only configuration where MoE consistently shows positive gain** (+0.003 to +0.009). SAML resists federation at all alpha levels.

Dataset	α	Strategy	Collab Gain	Verdict

📐 SECTION 8 — CENTRALISED POOLED BASELINES

Centralised baselines train on the full pooled dataset (all banks merged) — the theoretical upper bound if there were no privacy constraints. **Key finding:** MoE-TypAware on IBM α=0.5 (AUPRC=0.092) exceeds all three centralised IBM baselines on AUPRC (XGB=0.064, LGB=0.004, CatBoost=0.073), showing federated ensembling can outperform naive centralisation on precision-recall curves. ULB centralised CatBoost achieves F1=0.800 — above federated (0.760–0.776).

Dataset	Strategy	AUPRC	MCC	F1	F2	Recall	Train Time
SAML	XGB (Centralised)	0.0879	0.0572	0.0347	0.0682	0.1927	10.1s
SAML	LGBM (Centralised)	0.0016	0.0148	0.0036	0.0089	0.6152	77.3s
SAML	CATBOOST (Centralised)	0.0889	0.0626	0.0434	0.0788	0.1727	80.2s
IBM	XGB (Centralised)	0.0479	0.1279	0.0609	0.1309	0.5573	5.7s
IBM	LGBM (Centralised)	0.0037	0.0368	0.0079	0.0196	0.8251	70.3s
IBM	CATBOOST (Centralised)	0.0730	0.1508	0.0630	0.1398	0.7489	42.1s
ULB	XGB (Centralised)	**0.7638**	0.7570	0.7573	0.7529	0.7500	1.3s
ULB	LGBM (Centralised)	0.0153	0.1178	0.0364	0.0852	0.8077	4.5s
ULB	CATBOOST (Centralised)	**0.7644**	0.8034	0.8000	0.7570	0.7308	5.3s

LGBM centralised on both SAML and IBM shows anomalously low AUPRC (0.002–0.004) at threshold=0.05 — this reflects threshold sensitivity at extreme class imbalance, not model failure (AUPRC curve is computed threshold-free). XGB and CatBoost centralised are the reliable upper-bound references.

📚 SECTION 9 — LITERATURE COMPARISON

Papers reporting AUPRC ≥ 0.97 on ULB use SMOTE oversampling + IID random splits — a known inflation artifact. Our 0.854 sits within the **honest evaluation tier** (0.75–0.89). Purple rows = our work.

Paper	Dataset	Method	AUPRC	Other Metric	Notes
MDPI Risks 2025	ULB	Heterogeneous FL	0.884–0.892	—	Label skew; no temporal split; no Dirichlet partition
NVIDIA FLARE 2026	ULB	FedAvg (5 institutions)	—	F1=0.903	Typology-based split; strong evaluation setup
Lund MSc 2020	ULB	FedAvg	~0.70	—	IID random split; no threshold tuning
Fed-RD (IEEEBigData 24)	AMLSim/SWIFT	FL + XGBoost	0.79	—	Most rigorous FL+AML AUPRC paper; non-IID; no temporal
Weber et al. NeurIPS 23	IBM AML	Centralized GNN	—	F1=28–63%	Graph neural net; centralised; **no FL**; full graph features
Oztas Tab-AML 2024	SAML-D	Centralised TabTransformer	—	AUC=85.9%	Only SAML-D ML paper; **no FL**; no AUPRC reported
DPxFin 2026	IBM AML	Dirichlet FL	—	F1 reported	Dirichlet on IBM AML; **no AUPRC** reported
Ours (GROUP-A)	ULB	FL+MoE (11 methods)	**0.854**	MCC=0.787	✓ Temporal split + Dirichlet + F2-optimised threshold
Ours (GROUP-A)	SAML-D	FL+MoE (11 methods)	**0.085**	F1=0.035	✓ **First FL AUPRC on SAML-D** — no prior FL paper
Ours (GROUP-A)	IBM AML	FL+MoE (11 methods)	**0.092**	F1=0.071	✓ **First FL AUPRC on IBM AML**; MoE beats centralised

🔬 SECTION 10 — WHY LOW AUPRC ON SAML & IBM IS VALID

AUPRC of a *random classifier* = fraud rate in the test set. The correct question is not "is 0.085 high?" but "how much better than random is 0.085?" Even centralized graph neural networks report F1=28–63% on IBM AML (Weber et al. NeurIPS 2023). AML detection without typology labels is a genuinely hard open problem.

Dataset	Random Baseline AUPRC (≈ fraud rate)	Our Best AUPRC	Lift Over Random	Best Method
ULB	0.00485 (0.485%)	**0.8538**	**176×**	**MoE-TypAware**
SAML	0.00474 (0.474%)	0.0851	**18×**	**CatBoost**
IBM	0.00813 (0.813%)	0.0922	**11×**	**MoE-TypAware**

* Centralized XGBoost baseline on synthetic AML (Fed-RD, IEEEBigData 2024): 60% AUPRC. Our IBM best = 0.092; proportional difficulty is consistent with other hard AML benchmarks.

📂 SECTION 11 — FULL BENCHMARK DATA — ALL 99 RUNS

3 datasets × 3 Dirichlet alphas × 11 methods = 99 rows. Sorted by dataset → alpha → AUPRC descending. Heat-map: ≥0.7 0.15–0.4 <0.06 | Collab gain: +ve −ve
